

What is active cell balancing?

Active cell balancing is an optimal solution to achieve these goals, as it is the key to reducing battery heating and improving energy use efficiency. With active cell balancing, energy is evenly distributed among the cells rather than being converted into heat. It also allocates higher current levels as the energy is redistributed efficiently.

How does active balancing work?

With the energy stored in inductors, the active balancing system also consists of a transistor and driver microchip. The energy stored in the inductor is transferred to a specific cell, requiring a more complex controller to determine the energy destination and forward it to the defined cell.

What is passive balancing in a battery management system?

Source: Monolithic Power Systems Most battery management systems (BMS) today include passive balancing to periodically bring all cells in series to a common SOC value. Passive balancing does this by connecting a resistor across each individual cell as necessary to dissipate energy and lower the SOC of the cell.
